COURSE NOTES

Gauge Theories in Particle Physics

Willoughby Seago

January 16, 2023

These are my notes from the course gauge theories in particle physics. I took this course as a part of the theoretical physics degree at the University of Edinburgh.

These notes were last updated at 13:18 on January 25, 2023. For notes on other topics see .

Introduction

1.1 Other Relevant Courses

This course follows on directly from the *Quantum Field Theory* course, so much of the relevant background is contained in those notes. A lot of the notation is also taken from this course. It is also expected that students on this course will have taken *Symmetries of Particles and Fields*, and the prerequisite for that course, *Symmetries of Quantum Mechanics*, so for any group theory related topics see the notes of one of these courses. Other relevant courses will be flagged throughout the notes.

1.2 Conventions

- We will mostly work in natural units, where $c = \hbar = 1$.

- We use the mostly-minuses metric, $(+---)$, or $(+-\cdots-)$ in D spacetime dimensions.

- We will use the Einstein summation convention where repeated indices are summed over. In $d + 1$ dimensions Greek letters, $\mu, \nu, \rho, ...,$ run from 0 to d and Latin letters, $i, j, k, ...,$ run from 1 to d.

- We use the Fourier transform

$$\tilde{f}(p) = \int_{-\infty}^{\infty} \mathrm{d}x\, e^{ipx} f(x), \qquad \text{and} \qquad f(x) = \int_{-\infty}^{\infty} \frac{\mathrm{d}p}{2\pi} e^{-ipx} \tilde{f}(p). \tag{1.2.1}$$

- Feynman diagrams are drawn with time increasing to the right.

- The electric charge, e, is taken to be positive, so an electron has charge $-e$.

Part I

Quantum Electrodynamics

Two

Classical Electrodynamics

Quantum electrodynamics (QED) is the quantum field theory (QFT) of electromagnetism. It supersedes classical electrodynamics (CED) as a theory for predicting what happens to electric charges, as well as electromagnetic radiation, light. We'll start this section by discussing CED and some of its short comings which necessitate the development of QED. For more details on CED see the *Classical Electrodynamics* course.

2.1 Classical Action

Classical electrodynamics follows from the action

$$S = \int \mathrm{d}^4 x \left[-\frac{1}{4} F^{\mu\nu} F_{\mu\nu} - J_\mu A^\mu \right] \tag{2.1.1}$$

where A_μ is the electromagnetic field (also called the electromagnetic potential), J_μ is the current, and $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ is the electromagnetic field strength (confusingly also called the electromagnetic field in some contexts).

The first term in the action tells us how the electromagnetic field evolves and the second term encodes interactions. One common case is a current made of particles of charge q_i. The current due to the ith particle is $J^\mu = q_i u_i^\mu = q_i \mathrm{d} x_i^\mu / \mathrm{d} \tau_i$ (no sum on i). In this case we can write the interaction term as a sum over particles and the action from each particle is given by an integral over the particle's world line. Thus the action can be written as

$$S = \int \mathrm{d}^4 x \left[-\frac{1}{4} F^{\mu\nu} F_{\mu\nu} \right] - \sum_i \int \mathrm{d}\tau_i \, q_i A_\mu(x_i(\tau_i)) \frac{\mathrm{d} x_i^\mu(\tau_i)}{\mathrm{d}\tau_i} + \cdots . \tag{2.1.2}$$

The "$\cdots$" here accounts for other effects not already covered, such as spin corrections. These terms are suppressed by factors of $1/m_i$ or more, m_i being the mass of the ith particle.

2.2 Problems with CED

The theory of point-like electric charges developed as above is not entirely satisfactory. Recall that the Lorentz force on a particle with charge q_i and four-velocity u_i^μ in an electromagnetic field with field strength tensor $F^{\mu\nu}$ is

$$\frac{\mathrm{d} p_i^\mu}{\mathrm{d}\tau} = q_i F^{\mu\nu}(x_i(\tau)) u_{i\nu}(x_i(\tau)) \tag{2.2.1}$$

where $p_i = m_i u_i = m_i \mathrm{d}x_i/\mathrm{d}\tau$ is the four-momentum of the particle, with m_i being the mass of the ith particle. This law follows from conservation of energy, so it's pretty fundamental.

Now consider the Coulomb field of particle 1 in particle 1's rest frame. At a point x a distance r from particle 1, which has position x_1, the Coulomb field is

$$A^0(x) = \frac{q_i}{4\pi r} = \frac{q_i}{4\pi} \frac{1}{\sqrt{(x^1 - x_1^1)^2 + (x^2 - x_1^2)^2 + (x^3 - x_1^3)^2}}. \qquad (2.2.2)$$

If we can write this in a covariant way then it will apply in all frames. We can do this using $u_1 = (1, \mathbf{0})$, which is the four-velocity of the particle in it's rest frame in units where $c = 1$. We then have

$$[u_1 \cdot (x - x_1)]^2 - (x - x_1)^2 = (x^0 - x_1^0)^2 - (x^0 - x_1^0)^2 + (x^i - x_1^i)^2. \quad (2.2.3)$$

Using u_1^μ to get a μ index we have

$$A^\mu(x) = \frac{q_i}{4\pi} \frac{u_1^\mu}{\sqrt{[u_1 \cdot (x - x_1)]^2 - (x - x_1)^2}}. \qquad (2.2.4)$$

This is covariant and so holds in any inertial frame.

Now suppose that particles 1 and 2 interact. The force on particle one is

$$\frac{\mathrm{d}p_1^\mu}{\mathrm{d}\tau} = q_1 F^{\mu\nu}(x_1(\tau)) u_{1\nu}(\tau). \qquad (2.2.5)$$

The $F^{\mu\nu}$ appearing here is the total electromagnetic field strength. This proves to be a problem because part of $F^{\mu\nu}$ is the Coulomb field of particle 1, A^μ. We can see from the expression above that this is singular when $x = x_1$, which is exactly the case when we try to compute the force above. So we get a divergent result which we have to somehow make sense of.

The standard solution in CED to avoid this problem is to just use the electromagnetic field strength due to particle 2, and ignore the field from particle 1. Then, so long as the two particles can't have the same position, $F^{\mu\nu}$ is nonsingular and we avoid the problem with infinity. This workaround works well at low energies (small velocities).

The problem is that this workaround is not consistent with conservation of energy. For example, consider a classical atom, formed from a nucleus of charge Ze, which we take to have infinite mass, and an electron of charge $-e$. The Lorentz force applied to the electron, calculated using the electric field only from the nucleus, is consistent with stable circular orbits. The problem is that as the electron is orbiting it is changing direction, and so accelerating, and therefore must radiate. There is only one possible source for this energy, the potential, and so the orbit must decay.

Since the orbit decays there must be some force we have not accounted for causing this decay. It is possible to account for this force only if we include the electron's own field in the calculation of the force upon the electron. This means we have to account for interactions of particles with their own fields. The correction that we get when doing so is suppressed by inverse powers of c, which is why removing the electron's electromagnetic field works well enough for many purposes at low energies.

Once we accept that particles interact with their own fields there is another problem. The Coulomb field of a point-like particle contains an infinite electrostatic energy. The energy density of an electromagnetic field is $(E^2 + B^2)/2$, meaning that the energy contained in the Coulomb field outside of a spherical region of radius $r_{\min}$ centred on the electron is given by

$$\int \mathrm{d}^3 x \, \frac{1}{2} E^2 = \frac{1}{2} \frac{e^2}{(4\pi)^2} \int_{S^2} \mathrm{d}\Omega \int_{r_{\min}}^{\infty} \mathrm{d}r \, r^2 \frac{1}{r^4} = \frac{1}{8\pi} \frac{1}{r_{\min}}. \tag{2.2.6}$$

Taking $r_{\min} \to \infty$ the energy diverges.

The classical physics solution to this is to say that the electron isn't point-like. Then if we choose $r_{\min}$ to be the size of the electron so long as

$$mc^2 \gtrsim \frac{1}{2} \frac{e^2}{4\pi r_{\min}}, \tag{2.2.7}$$

so the energy of the field is less than the total energy available from the electron, things are fine. Setting $c = 1$ again gives

$$r_{\min} \gtrsim \frac{1}{2} \frac{e^2}{4\pi} \frac{1}{m} = \alpha \ell_{\text{Compton}} \tag{2.2.8}$$

where $\alpha = e^2/(4\pi)$ is the fine structure constant and ℓ_{Compton} is the Compton wavelength, which is the wavelength of a photon with the same energy as the rest mass of the particle. What this tells us is that scales at which quantum mechanical effects become important become important before the size of the electron becomes a problem classically, so if we're only interested in classical computations we don't need to worry about treating the electron as point-like.

However, we know from experiments that the electron is point-like at least up to the 1 TeV scale, which is about one millionth of the limit above. These point-like particles lead to divergences in classical theories, and also in quantum theories, like the ones above. Interestingly the divergence is actually not as bad in the quantum theory, being log divergent instead of going as $1/r_{\min}$. In the quantum theory we can deal with these infinities by absorbing them into a finite number of measured parameters, such as e and m, and we get a very powerful and predictive theory, QED.

Three

QFT Recap

It's part of my job to give you problems

Donal O'Connell

3.1 QED Lagrangian

In QFT, in particular in QED, we replace the classical action with the **QED action**:

$$S = \int d^D x \left[-\frac{1}{4} F^{\mu\nu} F_{\mu\nu} + \bar{\psi}(i\slashed{D} - m)\psi \right]. \tag{3.1.1}$$

Here $F^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu$ as before. The change comes in the interaction term, where we now have the spinor field ψ, which is acted on by the covariant derivative, which in QED is given by $D_\mu := \partial_\mu - ieA_\mu$. Recall that $\slashed{a} := \gamma^\mu a_\mu$ where γ^μ are the Dirac gamma matrices. Note that we leave the dimension as a variable, in preparation for dimensional regularisation later.

Notice that there are no world lines appearing in the action now. This reflects the fact that we've replaced the particles with definite position with fields, which aren't localised in the same way. One of the biggest changes upon moving to a *quantum* field theory is that we have a the new phenomenon of pair production. This creates new world lines, which is part of the reason we have to move away from actions involving sums over world lines.

We use the Dirac Lagrangian in QED since we are mostly interested in electrons, which are spin 1/2 particles. If instead we have a spin 0 particle with complex scalar field Φ then we can use the **scalar QED** Lagrangian

$$S = \int d^D x \left[-\frac{1}{4} F^{\mu\nu} F_{\mu\nu} + (D_\mu \Phi)^\dagger (D^\mu \Phi) - m^2 \Phi^\dagger \Phi - V(\Phi) \right] \tag{3.1.2}$$

where V is some potential.

If we neglect spin corrections in QED, often a valid thing to do since the spin is on the order of $\hbar$, then we get similar results in both normal and scalar QED, and these results are similar to those we get in classical electrodynamics. In this way scalar QED is more similar to classical electrodynamics, and we will make use of scalar QED as an example while focusing on normal QED for applications.

In some ways normal QED is actually simpler than scalar QED, there is no potential in normal QED and in normal QED the largest number of fields comes from the $-ie\bar{\psi}\slashed{A}\psi$ term, with three fields, whereas scalar QED has a four field term, $-\bar{\psi}A_{\mu}^{\dagger}A_{\mu}\psi$.

The main objects of physical interest in QFT are scattering amplitudes. We will make use of both canonical quantisation and path integral methods to compute these and other quantities.

3.2 Canonical Quantisation

We'll compute one term of a tree-level amplitude using the canonical quantisation approach. For more details and similar calculations see the first half of the *Quantum Field Theory* course. We'll consider a real scalar field with a cubic interaction

$$\mathcal{L}_{\text{int}} = -\frac{g}{3!}\varphi^3. \tag{3.2.1}$$

The two-to-two amplitude[1], $\mathcal{A}$, is given by

$$i\mathcal{A} = \langle p_1', p_2'|S|p_1, p_2\rangle \tag{3.2.2}$$

where p_i are the momenta of the incoming particles and p_i' the momenta of the outgoing particles. The S-matrix, S, is given by the Dyson expansion:

$$S = \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \text{T} \int dt_1 \cdots \int dt_n\, H_{\text{int}}(t_1) \cdots H_{\text{int}}(t_n) \tag{3.2.3}$$

$$= \sum_{n=0}^{\infty} \frac{i^n}{n!} \text{T} \int d^D x_1 \cdots \int dx_n\, \mathcal{L}_{\text{int}}(x_1) \cdots \mathcal{L}_{\text{int}}(x_n) \tag{3.2.4}$$

$$= \text{T}\exp\left\{i\int d^D x\, \mathcal{L}_{\text{int}}\right\} \tag{3.2.5}$$

$$= \text{T}\exp\{iS_{\text{int}}\} \tag{3.2.6}$$

where T is the time ordering operator, acting on everything to its right, H_{int} is the interaction Hamiltonian, related to the interaction Lagrangian by

$$\int d^{D-1}x\, \mathcal{L}_{\text{int}} = -H_{\text{int}} \tag{3.2.7}$$

and S_{int} is the interaction action, given by

$$S_{\text{int}} := \int d^D x\, \mathcal{L}_{\text{int}}. \tag{3.2.8}$$

Note that the exponential is just a short hand for the expansion above based on the similarity with the Taylor series of the exponential.

Suppose we are interested in $i\mathcal{A}$ at order g^2. Then we consider the following term:

$$i\mathcal{A}^{(2)} =$$
$$\langle p_1', p_2'|\frac{i^2}{2}\left(-\frac{g}{3!}\right)^2 \int d^D x_1 \int d^D x_2\, \text{T}\,\varphi(x_1)\varphi(x_1)\varphi(x_1)\varphi(x_2)\varphi(x_2)\varphi(x_2)|p_1, p_2\rangle.$$

[1] two changes here from *Quantum Field Theory*, in that course we called the amplitude $\mathcal{M}$ and the factor of i was missing, this phase doesn't effect the final physics which always depend on $|\mathcal{A}|^2$

We compute this using contractions. One particular set of contractions is

$$\langle p_1', p_2' | \frac{i^2}{2} \left(-\frac{g}{3!}\right)^2 \int \mathrm{d}^D x_1 \int \mathrm{d}^D x_2 \; \mathrm{T}\, \varphi(x_1)\varphi(x_1)\varphi(x_1)\varphi(x_2)\varphi(x_2)\varphi(x_2)|p_1, p_2\rangle.$$

We can interpret this in terms of creation and annihilation of particles. The fields at x_2 contracted with the incoming particles annihilate them and then the fields at x_1 contracted with the outgoing particles create the outgoing particles. The contraction between the fields at x_1 and x_2 gives a propagator between these points. This is best seen in a Feynman diagram,

$$(3.2.9)$$

The initial particles enter on the left, annihilate at x_1, where there is a propagator to x_2, where two new particles are created.

3.3 Path Integral

In the path integral formulation we don't compute amplitudes directly. Instead we compute correlators, which we can extract the amplitude from later. For more details and similar calculations see the second half of the *Quantum Field Theory* course. The starting point for using the path integral formalism is to define the generating functional, which for QED is

$$Z[J] = \int \mathcal{D}\varphi \exp\left\{i \int \mathrm{d}^D x \left[\mathcal{L}(\varphi) + J(x)\varphi(x)\right]\right\}. \tag{3.3.1}$$

We then define the n point **correlator**

$$G^{(n)}(x_1, \ldots, x_n) := \langle 0 | \mathrm{T}\, \varphi(x_1) \cdots \varphi(x_n) | 0 \rangle \tag{3.3.2}$$

$$=: \langle \varphi(x_1) \cdots \varphi(x_n) \rangle \tag{3.3.3}$$

$$= \frac{1}{Z[0]} \left(\frac{1}{i}\frac{\delta}{\delta J(x_1)}\right) \cdots \left(\frac{1}{i}\frac{\delta}{\delta J(x_n)}\right) Z[J] \bigg|_{J=0} \tag{3.3.4}$$

$$= \int \mathcal{D}\varphi\, \varphi(x_1) \cdots \varphi(x_n) \exp\left\{i \int \mathrm{d}^D x \left(\mathcal{L}_{\mathrm{free}} + \mathcal{L}_{\mathrm{int}}\right)\right\}.$$

The factor of $1/Z[0]$ is just normalisation and we typically don't worry about it. The source is just there to allow us to pull down factors of φ by differentiating, which is why we set it to zero at the end.

As the first example of the path integral we'll compute the three-point correlator to first order in g. We'll choose our normalisation such that $Z[0] = 1$. Then

$$G^{(3)}(x_1, x_2, x_3) = \int \mathcal{D}\varphi\, \varphi(x_1)\varphi(x_2)\varphi(x_3) \mathrm{e}^{iS_{\mathrm{free}} + iS_{\mathrm{int}}}. \tag{3.3.5}$$

Expanding the interaction exponential to first order we get

$$G^{(3)}(x_1, x_2, x_3) \approx \int \mathcal{D}\varphi\, \varphi(x_1)\varphi(x_2)\varphi(x_3)\left[1 - \frac{ig}{3!}\int \mathrm{d}^D x \varphi(x)^3\right] e^{iS_{\text{free}}}. \quad (3.3.6)$$

We have now reduced this to a Gaussian path integral which can be computed with contractions. One set of contractions gives the result

$$C(x_1, x_2, x_3) = -ig \int \mathcal{D}\varphi\, \overline{\varphi(x_1)\overline{\varphi(x_2)}\overline{\varphi(x_3)} \int \mathrm{d}^D x\, \varphi(x)}\varphi(x)\varphi(x)e^{iS_{\text{free}}}. \quad (3.3.7)$$

The contraction of two fields is given by the **Feynman propagator**:

$$\overline{\varphi(x)\varphi}(y) = i\Delta(x - y) = \int \frac{\mathrm{d}^D p}{(2\pi)} \frac{i}{p^2 - m^2 + i\varepsilon} e^{ip\cdot(x_1 - x_2)}. \quad (3.3.8)$$

Here ε is a small positive real number included to make expressions converge. Note that $\Delta(x - y) = \Delta(y - x)$. At this point we introduce the short hand notation $\hat{\mathrm{d}}p = \mathrm{d}p/(2\pi)$.

Using this result the contraction above can be calculated as

$$C(x_1, x_2, x_3) = -ig \int \mathrm{d}^D x\, i\Delta(x_1 - x)\, i\Delta(x_2 - x)\, i\Delta(x_3 - x). \quad (3.3.9)$$

We can again summarise this in a diagram

$$(3.3.10)$$

In fact, given a diagram we can read off the corresponding expression for a correlator through the following prescription:

- Each line, $x \text{ ----- } y$, is a factor of $i\Delta(x - y)$.

- Each vertex, x, is a factor of $-ig \int \mathrm{d}^D x$.

- Conserve momentum at each vertex.

There are other possible contractions, one such contraction contributing to $\langle \varphi(x_1)\varphi(x_2)\varphi(x_3)\rangle$ is

$$-ig \int \mathcal{D}\varphi\, \varphi(x_1)\varphi(x_2)\varphi(x_3) \int \mathrm{d}^D x\, \varphi(x)\varphi(x)\varphi(x)e^{iS_{\text{free}}} \quad (3.3.11)$$

$$= -ig \int \mathrm{d}^D x\, i\Delta(x_1 - x)\, i\Delta(x - x)\, i\Delta(x_2 - x_3) \quad (3.3.12)$$

$$= \begin{matrix} x_1 \text{ --- } x \\ x_2 \text{ ----- } x_3 \end{matrix} . \quad (3.3.13)$$

This diagram is disconnected. Often we are only interested in correlators involving connected diagrams, since these are the only diagrams that contribute to quantities such as $\log(Z[J])$, as we saw in *Quantum Field Theory*.

For another example consider the four-point correlator

$$G^{(4)}(y_1, y_2, z_1, z_2) = \langle 0 | \, T \, \varphi(y_1)\varphi(y_2)\varphi(z_1)\varphi(z_2) | 0 \rangle \tag{3.3.14}$$

$$= \int \mathcal{D}\varphi \, \varphi(y_1)\varphi(y_2)\varphi(z_1)\varphi(z_2) \exp\left\{ i \int \mathrm{d}^D x (\mathcal{L}_{\text{free}} + \mathcal{L}_{\text{int}}) \right\}. \tag{3.3.15}$$

If we want to evaluate the order g^2 contribution to this correlator then we can do so by considering the quadratic term after expanding $\exp\{iS_{\text{int}}\}$:

$$\int \mathcal{D}\varphi \varphi(y_1)\varphi(y_2)\varphi(z_1)\varphi(z_2)$$

$$\times \left[\frac{1}{2}\left(-\frac{ig}{3!}\right)^2 \int \mathrm{d}^D x_1 \int \mathrm{d}^D x_2 \, \varphi(x_1)\varphi(x_1)\varphi(x_1)\varphi(x_2)\varphi(x_2)\varphi(x_2) \right] e^{iS_{\text{free}}}$$

Again this is a Gaussian integral and can be computed using contractions. One particular contraction we may want to consider is

$$\varphi(y_1)\varphi(y_2)\varphi(z_1)\varphi(z_2) \, \varphi(x_1)\varphi(x_1)\varphi(x_1)\varphi(x_2)\varphi(x_2)\varphi(x_2) \tag{3.3.16}$$

where we've only written the fields, not any of the integrals, constants, or exponentials, to fit it all on one line. This corresponds to the diagram

$$D = \qquad\qquad\qquad . \tag{3.3.17}$$

There are multiple different contractions which all give the same diagram, and so the same contribution to the correlator. We combine these into one, including a **symmetry factor** counting the number of such diagrams. The factor of $1/3!$ has been chosen to cancel out this symmetry factor, in this case because we can permute the three $\varphi(x_1)$ fields and the three $\varphi(x_2)$ fields without changing anything, giving $(3!)^2$ as a symmetry factor, which cancels the $(3!)^2$ from expanding the exponential at second order. The result of evaluating all contractions giving diagram D is

$$D = \int \mathrm{d}^D x_1 \int \mathrm{d}^D x_2 \, (-ig)^2 \, i\Delta(y_1 - x_2) \, i\Delta(y_2 - x_3) \, i\Delta(x_2 - x_1) \, i\Delta(x_1 - z_1) \, iD(x_1 - z_2).$$

Usually we prefer to work in momentum space. The simplest way to move to momentum space here is to replace each propagator with the inverse Fourier transform of the Fourier transform:

$$\Delta(x - y) = \int \hat{\mathrm{d}}p \, e^{ip \cdot (x-y)} \underbrace{\frac{1}{p^2 - m^2 + i\varepsilon}}_{=\tilde{\Delta}(p)} . \tag{3.3.18}$$

We can then manipulate the result until it is of the form $D = \mathcal{F}^{-1}\{\widetilde{D}\}$ and then identify $\widetilde{D} = \mathcal{F}\{D\}$. Making this replacement of propagators we get the somewhat unwieldy

$$
D = (-ig)^2 \int d^D x_1 \, d^D x_2 \int \hat{d}p_1 \, \hat{d}p_2 \, \hat{d}p_3 \, \hat{d}p_4 \, \hat{d}q
$$
$$
\times \, i e^{ip_1 \cdot (y_1 - x_2)} i e^{ip_2 \cdot (y_2 - x_2)} i e^{ip_3 \cdot (x_1 - z_1)} i e^{ip_4 \cdot (x_1 - z_2)} i e^{iq \cdot (x_2 - x_1)}
$$
$$
\times \, \frac{1}{q^2 - m^2 + i\varepsilon} \prod_{j=1}^{4} \frac{1}{p_j^2 - m^2 + i\varepsilon}. \tag{3.3.19}
$$

We use q for the momentum of the internal propagator to distinguish it from the external propagators. We can perform the integrals over x_i using the identity

$$
\int d^D x \, e^{ip \cdot x} = (2\pi)^D \delta(p). \tag{3.3.20}
$$

Rewriting the exponentials slightly we get

$$
e^{-i(p_1 + p_2 - q) \cdot x_2} i e^{ip_1 \cdot y_1} i e^{ip_2 \cdot y_2} e^{i(p_3 + p_4 - q) \cdot x_1} i e^{-ip_3 \cdot z_1} i e^{-ip_4 \cdot z_2} i \tag{3.3.21}
$$

so we'll get two Dirac deltas:

$$
D = (-ig)^2 \int \hat{d}p_1 \, \hat{d}p_2 \, \hat{d}p_2 \, \hat{d}p_3 \, \hat{d}p_4 \, \hat{d}q \, (2\pi)^D \delta(p_1 + p_2 - q)
$$
$$
\times \, (2\pi)^D \delta(p_3 + p_4 - q) e^{ip_1 \cdot y_1} e^{ip_2 \cdot y_2} e^{-ip_3 \cdot z_1} e^{-ip_4 \cdot z_2}
$$
$$
\times \, \frac{i}{q^2 - m^2 + i\varepsilon} \prod_{j=1}^{4} \frac{i}{p_j^2 - m^2 + i\varepsilon}. \tag{3.3.22}
$$

We can then perform the q integral using the second Dirac delta to set $q = p_3 + p_4$, giving

$$
D = (-ig)^2 \int \hat{d}p_1 \, \hat{d}p_2 \, \hat{d}p_3 \, \hat{d}p_4 \, \hat{d}q \, (2\pi)^D \delta(p_1 + p_2 - p_3 - p_4)
$$
$$
\times \, e^{ip_1 \cdot y_1} e^{ip_2 \cdot y_2} e^{-ip_3 \cdot z_1} e^{-ip_4 \cdot z_2}
$$
$$
\times \, \frac{i}{(p_3 + p_4)^2 - m^2 + i\varepsilon} \prod_{j=1}^{4} \frac{i}{p_j^2 - m^2 + i\varepsilon}. \tag{3.3.23}
$$

Note that the factor of $(2\pi)^D$ in front of the Dirac delta cancels with the hidden factor of $1/(2\pi)^D$ in $\hat{d}p$. This is now of the form $D = \mathcal{F}^{-1}\{\widetilde{D}\}$, so we can identify $\widetilde{D} = \mathcal{F}\{D\}$ as

$$
\widetilde{D}(p_1, p_2, p_3, p_4) = (2\pi)^D \delta(p_1 + p_2 - p_3 - p_4) \frac{i}{(p_3 + p_4)^2 - m^2 + i\varepsilon} \prod_{j=1}^{4} \frac{i}{p_j^2 - m^2 + i\varepsilon}. \tag{3.3.24}
$$

Notice that the signs of p_i in the Dirac delta reflect a sign choice where p_1 and p_2 are incoming momenta and p_3 and p_4 are outgoing momenta. If all momenta are chosen to be incoming, as is sometimes the case, then all of the signs would be $+$. This Dirac delta is simply telling us that the total momentum is conserved, so it's not that interesting and is not considered to be part of the amplitude.

Similarly, the external line factors, the product above, don't carry any information, beyond the number of external lines, and aren't present in the amplitude. For this reason we consider **amputated correlators**, which are given by omitting this term in momentum space. In position space it's slightly more work to amputate a correlator, but it can be done by using

$$(\partial_x^2 + m^2)\, i\Delta(x - y) = i \int \hat{\mathrm{d}}^D p\, (-p^2 + m^2) \frac{\mathrm{e}^{-ip \cdot (x-y)}}{p^2 - m^2 + i\varepsilon} = -i\delta(x - y), \quad (3.3.25)$$

where ∂_x^2 is the d'Alembert operator with respect to x, rather than $\partial/\partial x$ squared. This statement is simply that the propagator is a Green's function of the Klein–Gordon operator, which should be familiar from *Quantum Field Theory*. We also see from this that the "inverse" of $\partial^2 + m^2$ is $1/(p^2 - m^2 + i\varepsilon)$, another fact we saw in the previous course. Using this we can amputate a correlator in position space by acting on it with

$$\prod_{j=1}^{n} (+i)(\partial_j^2 + m_j^2) \qquad\qquad\qquad (3.3.26)$$

where ∂_j^2 is the d'Alembert with respect to x_j and m_j is the mass of the jth particle.

Four

Quantum Electrodynamics

4.1 The QED Lagrangian

The QED Lagrangian is

$$\mathcal{L} = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} + \bar{\psi}(i\slashed{D} - m)\psi \tag{4.1.1}$$

where $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$ and $D_\mu = \partial_\mu - ieA_\mu$. One important property of this Lagrangian is the presence of a $\mathrm{U}(1)$ gauge symmetry, given by

$$\psi(x) \mapsto \psi(x)e^{i\alpha(x)}, \quad \bar{\psi}(x) \mapsto \bar{\psi}(x)e^{-i\alpha(x)}, \quad \text{and} \quad A_\mu(x) \mapsto A_\mu(x) + \frac{1}{e}\partial_\mu\alpha(x)$$

where α is some function of spacetime taking values in $[0, 2\pi)$ (with continuous second derivatives). We can see that this leaves the Lagrangian invariant by considering how each term transforms. First,

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu \tag{4.1.2}$$

$$\mapsto \partial_\mu\left(A_\nu + \frac{1}{e}\partial_\nu\alpha\right) - \partial_\nu\left(A_\mu + \frac{1}{e}\partial_\mu\alpha\right) \tag{4.1.3}$$

$$= \partial_\mu A_\nu + \frac{1}{e}\partial_\mu\partial_\nu\alpha - \partial_\nu A_\mu - \frac{1}{e}\partial_\mu\alpha \tag{4.1.4}$$

$$= F_{\mu\nu}. \tag{4.1.5}$$

Second,

$$\bar{\psi}(i\slashed{D} - m)\psi = \bar{\psi}(i\slashed{\partial} + e\slashed{A})\psi \tag{4.1.6}$$

$$\mapsto \bar{\psi}e^{-i\alpha}\left(i\slashed{\partial} + e\left(\slashed{A} + \frac{1}{e}\slashed{\partial}\alpha\right) - m\right)\psi e^{i\alpha} \tag{4.1.7}$$

$$= \bar{\psi}e^{-i\alpha}(i\slashed{\partial} + e\slashed{A} + \slashed{\partial}\alpha - m)\psi e^{i\alpha} \tag{4.1.8}$$

$$= \bar{\psi}e^{-i\alpha}e^{i\alpha}(i\slashed{\partial}(i\alpha) + i\slashed{\partial} + e\slashed{A} + \slashed{\partial}\alpha - m)\psi \tag{4.1.9}$$

$$= \bar{\psi}(\slashed{\partial} + e\slashed{A} - m)\psi \tag{4.1.10}$$

$$= \bar{\psi}(i\slashed{D} - m)\psi. \tag{4.1.11}$$

4.2 Divergences

Our focus in the first part of this course will be on renormalisation of divergences in QED. We will mainly look at correlators and how we can extract physics from renormalised correlators. We will do this through the process of renormalised perturbation theory.

Loop diagrams, such as
(4.2.1)

are often divergent. We can absorb these divergences into a finite (in QED) set of measured parameters.

To do this we distinguish between the fields and parameters appearing in the original Lagrangian, which we call **bare** fields and parameters, and the renormalised fields and parameters. Add a label B to each bare quantity so the Lagrangian is

$$\mathcal{L} = -\frac{1}{4} F_{\mathrm{B}\mu\nu} F_{\mathrm{B}}^{\mu\nu} + \bar{\psi}_{\mathrm{B}}(i\slashed{D}_{\mathrm{B}} - m_{\mathrm{B}})\psi_{\mathrm{B}} \qquad (4.2.2)$$

where $F_{\mathrm{B}\mu\nu} = \partial_\mu A_{\mathrm{B}\nu} - \partial_\nu A_{\mathrm{B}\mu}$ and $D_{\mathrm{B}\mu} = \partial_\mu - ie_{\mathrm{B}}A_{\mathrm{B}\mu}$. We can think of the original Lagrangian and the bare quantities as being "true", corresponding to some high energy theory. Then the renormalised quantities are from the low energy limit of this theory. We define the following renormalised quantities in terms of the bare quantities:

$$A_{\mathrm{B}\mu} = \sqrt{Z_3}A_\mu, \qquad (4.2.3)$$

$$\psi_{\mathrm{B}} = \sqrt{Z_2}\psi, \qquad (4.2.4)$$

$$m_{\mathrm{B}} = m + \delta m, \qquad (4.2.5)$$

$$e_{\mathrm{B}} = Z_e e. \qquad (4.2.6)$$

We fix the values of the unknown parameters introduced in these definitions by requiring that correlators of renormalised fields are finite and choosing these unknown parameters in such a way that this is enforced.

In *Quantum Field Theory* we didn't give a special notation for the bare quantities, and instead labelled the renormalised quantities, for example, φ_{R} was the renormalised scalar field and φ was the bare scalar field. This was because we didn't cover renormalisation until the end of the course, so the extra B labels would have been a nuisance. In this course we start with renormalisation, so we will work with the renormalised quantities more, so we don't give them a special label and instead label the bare quantities.

The parameters Z_2 and Z_3 are called the **wave function renormalisation constants**. The labels 2 and 3 are convention, and we'll introduce Z_1 shortly. The square roots are chosen as these fields appear squared in the Lagrangian.

The definition of the renormalised mass above doesn't fit the pattern. We've chosen to think of the renormalised mass, m, as simply being shifted by δm from the bare mass, m_B. We could have followed the pattern and written $m_B = Z_m m$ with $Z_m = 1 + \delta m / m$. This is nice in QED where if $m_B = 0$ then $m = 0$. However in other theories, such as scalar QED this isn't the case, it is possible for the bare field to be massless but the renormalised field has a mass. This can work with $m_B = Z_m m$, we just have to choose Z_m so that it diverges when $m_B = 0$. The reason that we don't define A_μ and ψ in the same way, i.e. $A_{B\mu} = A_\mu + \delta A_\mu$ and $\psi_B = \psi + \delta\psi$, is because we don't have any other vectors or spinors in our theory to give us δA_μ or $\delta\psi$. The reason we don't define e in this way is that when $e_B = 0$ the theory is non-interacting, and thus we should also have $e = 0$. Later we will expand Z_i as $1 + \delta_i$, which corresponds to $\delta_m = \delta m / m$.

To make the Z_i and δm well defined we need to pick a regulator. We'll use **dimensional regularisation**, or **dim reg**. We also need to pick a renormalisation scheme. We'll use **modified minimal subtraction**, or $\overline{\text{MS}}$.

In dim reg it is actually better to set

$$e_B = Z_e e \mu^\varepsilon \tag{4.2.7}$$

since e_B is dimensionless in $D = 4$, but in $D = 4 - 2\varepsilon$ dimensions e_B has mass dimension ε. We choose μ to be a mass scale so that e is dimensionless in $D = 4 - 2\varepsilon$ dimensions. Importantly μ is not a parameter of the bare theory. This means that no physics can depend on μ so μ must cancel out in any computation giving a measurable result. The choice of μ can effect how quickly perturbation theory converges, for terms of the form $\log(m/\mu)$ are common, and if we choose $\mu \approx m$ then this value will be small, whereas if $\mu \gg m$ we'll get large logs, which we usually want to avoid. The parameter μ is called the **renormalisation point** or occasionally the **'t Hooft scale**.

The Lagrangian can the be rewritten in terms of the renormalised quantities. First,

$$F_{B\mu\nu} = \partial_\mu A_{B\nu} - \partial_\nu A_{B\mu} = \partial_\mu(\sqrt{Z_3} A_\mu) - \partial_\nu(\sqrt{Z_3} A_\nu) = \sqrt{Z_3} F_{\mu\nu}, \tag{4.2.8}$$

and so

$$F_{B\mu\nu} F_B^{\mu\nu} = Z_3 F_{\mu\nu} F^{\mu\nu}. \tag{4.2.9}$$

We also have

$$i\slashed{D}_B = i\slashed{\partial} + e_B \slashed{A}_B = i\slashed{\partial} + Z_e \sqrt{Z_3} e \mu^\varepsilon \slashed{A} \tag{4.2.10}$$

so $\bar\psi_B i\slashed{D}_B \psi_B = Z_e Z_2 \sqrt{Z_3}$. We define $Z_1 = Z_e Z_2 \sqrt{Z_3}$ for notational compactness. One imagines that this process was followed in the reverse when Z_i were named. The mass term gives

$$\bar\psi_B m_B \psi_B = Z_2 m \bar\psi\psi + Z_2 \delta m \bar\psi\psi. \tag{4.2.11}$$

So the Lagrangian in terms of the renormalised quantities is

$$\mathcal{L} = -\frac{1}{4} Z_3 F^{\mu\nu} F_{\mu\nu} + Z_2 \bar\psi(i\slashed{\partial} - m)\psi + Z_1 e\mu^\varepsilon \bar\psi \slashed{A} \psi - Z_2 \delta m \bar\psi\psi. \tag{4.2.12}$$

It is not immediately clear that this Lagrangian has a gauge symmetry, but of course it does, since it inherits the gauge symmetry of the bare theory. This will be

made more clear later when we show that $Z_1 = Z_2$, which allows us to write this with a covariant derivative again.

To make sense of this we define $Z_i = 1 + \delta_i$ and then the Lagrangian is

$$\mathcal{L} = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} + \bar{\psi}(i\slashed{\partial} - m)\psi$$
$$- \frac{1}{4}\delta_3 F^{\mu\nu}F_{\mu\nu} + \delta_2\bar{\psi}(i\slashed{\partial} - m)\psi + \delta_1 e\mu^\varepsilon\bar{\psi}\slashed{A}\psi - \delta m\bar{\psi}\psi - \delta m\delta_2\bar{\psi}\psi. \quad (4.2.13)$$

This is of the form

$$\mathcal{L} = \mathcal{L}_{\text{classical}} + \mathcal{L}_{\text{ct}} \qquad (4.2.14)$$

where

$$\mathcal{L}_{\text{classical}} = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} + \bar{\psi}(i\slashed{\partial} - m)\psi \qquad (4.2.15)$$

is the "classical" Lagrangian, being of the same form as the Lagrangian in terms of the bare parameters and

$$\mathcal{L}_{\text{ct}} = -\frac{1}{4}\delta_3 F^{\mu\nu}F_{\mu\nu} + \delta_2\bar{\psi}(i\slashed{D} - m)\psi + \delta_1 e\mu^\varepsilon\bar{\psi}\slashed{A}\psi - \delta m\bar{\psi}\psi - \delta m\delta_2\bar{\psi}\psi \quad (4.2.16)$$

are the **counterterms**, which we choose in such a way that the divergences cancel out.

Note that in this expression $D_\mu = \partial_\mu - ie\mu^\varepsilon A_\mu$, with the factor of μ^ε. It is common to miss out writing in μ^ε both here and in the Lagrangian since it can always be inserted by dimensional analysis and disappears in final results. For tree diagrams we can take $\varepsilon \to 0$ anyway since there are no divergences, making it even more common to leave μ^ε out.

In QED divergences first appear at one loop, and since a single loop with external particles has at least two vertices these divergences are $\mathcal{O}(e^2)$. Since we choose the renormalisation parameters to cancel these divergences they must be of the form $Z_i = 1 + \mathcal{O}(e^2)$, with the 1 giving us the bare theory and the $\mathcal{O}(e^2)$ cancelling the divergences. This means that $\delta m\delta_2$ is $\mathcal{O}(e^4)$, so it is only important if we are doing a next-to-next-to leading order (NNLO) calculation or working with two or more loops. We'll only be doing leading order computations with one loop, so we'll neglect the final term of the Lagrangian.

4.3   Feynman Rules

The Feynman rules tell us how a diagram translates into an equation. For a given term involving a product of fields, such as $\bar{\psi}\slashed{A}\psi$, the Feynman rules can be derived by considering the tree level correlator $\langle\bar{\psi}\slashed{A}\psi\rangle$. Since this is at tree level the terms just add linearly allowing us to consider them one at a time. We then amputate the correlator, working in momentum space, and drop the overall momentum conservation Dirac delta. What is left is the Feynman rule for this term.

4.3.1 $\bar{\psi}\psi$ Term

First we'll consider the $\bar{\psi}\psi$ terms in the Lagrangian. These correspond to an interaction with the action

$$S_{\text{int}} = \int \mathrm{d}^D x \left[i\delta_2\bar{\psi}\slashed{\partial}\psi - (\delta_2 m + \delta m)\bar{\psi}\psi\right]. \qquad (4.3.1)$$

Diagrammatically this corresponds to the correlator

$$\xrightarrow{\quad p \quad} \otimes \xrightarrow{\quad p' \quad}. \tag{4.3.2}$$

The symbol $\otimes$ is used to signify a counter term, since these are often 1-to-1 scattering processes which would otherwise look like just a propagator.

Recall that in the canonical quantisation formalism we can expand ψ in terms of the electron annihilation operator, $a_s(p)$, and the positron creation operator, $b_s^\dagger(p)$:

$$\psi(x) = \sum_s \int \frac{\hat{\mathrm{d}}p}{2E_p} \left[a_s(p)u(p,s)\mathrm{e}^{-ip\cdot x} + b_s^\dagger(p)v(p,s)\mathrm{e}^{ip\cdot x} \right]. \tag{4.3.3}$$

Then we have

$$\slashed{\partial}\psi(x) = \sum_s \int \frac{\hat{\mathrm{d}}p}{2E_p} \left[-i\slashed{p}a_s(p)u(p,s)\mathrm{e}^{-ip\cdot x} + i\slashed{p}b_s^\dagger(p)v(p,s)\mathrm{e}^{ip\cdot x} \right]. \tag{4.3.4}$$

We want to calculate $\langle \bar{\psi}\slashed{A}\psi \rangle$ to tree level. To do this we expand $\mathrm{e}^{iS} = 1 + iS + \cdots$ to first order and consider the first order term, which corresponds to tree level processes (zeroth order corresponds to no interaction occurring). So for an incoming particle with momentum p and outgoing particle with momentum p' we need to calculate

$$\langle p'|i \int \mathrm{d}^D x \left[i\delta_2\bar{\psi}\slashed{\partial}\psi - (\delta_2 m + \delta m)\bar{\psi}\psi \right] |p\rangle. \tag{4.3.5}$$

To do this we need to contract the fields. We have an incoming and outgoing electron, which need to be created and destroyed and this can only be done one way. The field ψ can annihilate the incoming electron and the adjoint $\bar{\psi}$ can create the outgoing electron. Thus we must contract as follows:

$$\langle p'|i \int \mathrm{d}^D x\, i\delta_2\bar{\psi}\slashed{\partial}\psi|p\rangle - \langle p'|i \int \mathrm{d}^D x\, (\delta_2 m + \delta m)\bar{\psi}\psi|p\rangle. \tag{4.3.6}$$

Completing this contraction, and including the factor of $i\slashed{p}$ we get from acting with the derivative we get the result

$$i \int \mathrm{d}^D x \left[\delta_2(\slashed{p} - m) - \delta m \right] \bar{u}u\,\mathrm{e}^{-i(p-p')\cdot x}. \tag{4.3.7}$$

Performing this integral we get

$$i(2\pi)^D \delta(p - p') \left[\delta_2(\slashed{p} - m) - \delta m \right] \bar{u}u. \tag{4.3.8}$$

To get the Feynman rule we strip off the factors corresponding to external legs, since these are dealt with by other Feynman rules, so we remove $\bar{u}u$, and we strip off the overall momentum conserving Dirac delta $(2\pi)^D \delta(p - p')$, since this is enforced by conserving momentum at each vertex, which in this case just corresponds to setting $p = p'$. The resulting Feynman rule is

$$\xrightarrow{\quad p \quad} \otimes \xrightarrow{\quad p \quad} = i[\delta_2(\slashed{p} - m) - \delta m]. \tag{4.3.9}$$

4.3.2 $F^{\mu\nu}F_{\mu\nu}$ Term

> *Well you can't stop me. No one said*
> *we were going to use sane notation,*
> *just consistent notation.*
>
> Donal O'Connell

Now consider the $F^{\mu\nu}F_{\mu\nu}$ counterterm, which corresponds to the interaction action

$$S_{\text{int}} = \int \mathrm{d}^D x \left[-\frac{1}{4} \delta_3 F^{\mu\nu} F_{\mu\nu} \right]. \tag{4.3.10}$$

To calculate the Feynman rule associated with this interaction consider the diagram

$$\overset{k,\varepsilon}{\longrightarrow} \quad \overset{k',\varepsilon'}{\longrightarrow}$$
$$\sim\!\!\sim\!\!\otimes\!\!\sim\!\!\sim. \tag{4.3.11}$$

Here k and k' are momenta and ε and ε' are polarisation vectors. To first order this diagram gives

$$\langle k',\varepsilon'| i \int \mathrm{d}^D x \left[-\frac{1}{4} \delta_3 F^{\mu\nu} F_{\mu\nu} \right] |k,\varepsilon\rangle. \tag{4.3.12}$$

There are two possible ways to perform contractions on this:

$$\langle k',\varepsilon'| i \int \mathrm{d}^D x \left[-\frac{1}{4} \delta_3 F^{\mu\nu} F_{\mu\nu} \right] |k,\varepsilon\rangle, \tag{4.3.13}$$

$$\langle k',\varepsilon'| i \int \mathrm{d}^D x \left[-\frac{1}{4} \delta_3 F^{\mu\nu} F_{\mu\nu} \right] |k,\varepsilon\rangle. \tag{4.3.14}$$

Since we can freely commute F with itself and raise and lower the paired indices these two contractions are actually exactly the same. So we include a symmetry factor of 2 and only consider one of these contractions. We'll take the first contraction and compute

$$-i\frac{\delta_3}{2} \langle k',\varepsilon'| \int \mathrm{d}^D x \, F^{\mu\nu} F_{\mu\nu} |k,\varepsilon\rangle. \tag{4.3.15}$$

The next simplification is that for any two index tensor X we have

$$(X^{\mu\nu} - X^{\nu\mu})(X_{\mu\nu} - X_{\nu\mu}) = X^{\mu\nu}(X_{\mu\nu} - X_{\nu\mu}) - X^{\nu\mu}(X_{\mu\nu} - X_{\nu\mu}) \tag{4.3.16}$$

exchanging μ and ν in the second term

$$(X^{\mu\nu} - X^{\nu\mu})(X_{\mu\nu} - X_{\nu\mu}) = X^{\mu\nu}(X_{\mu\nu} - X_{\nu\mu}) - X^{\mu\nu}(X_{\nu\mu} - X_{\mu\nu}) \tag{4.3.17}$$

$$= 2 X^{\mu\nu}(X_{\mu\nu} - X_{\nu\mu}) \tag{4.3.18}$$

so, taking $X^{\mu\nu} = \partial^\mu A^\nu$, we have

$$F^{\mu\nu} F_{\mu\nu} = 2(\partial^\mu A^\nu)(\partial_\mu A_\nu - \partial_\nu A_\mu). \tag{4.3.19}$$

Hence the correlator is

$$-i\delta_3 \langle k', \varepsilon' | \int d^D x \partial^\mu A^\nu \overbrace{(\partial_\mu A_\nu - \partial_\nu A_\mu)} | k, \varepsilon \rangle. \tag{4.3.20}$$

As with the ψ case the derivatives act on the mode expansion to bring down a factor of $\pm i k_\mu$ from terms like $\varepsilon^\mu(k) a_s(k) e^{-ik \cdot x}$. The result of performing the contractions is

$$-i\delta_3 \int d^D x \, k'^\mu \varepsilon'^\nu (k_\mu \varepsilon_\nu - k_\nu \varepsilon_\mu) e^{-ik \cdot x} e^{ik' \cdot x}. \tag{4.3.21}$$

Performing the integral gives a Dirac delta, and we'll also expand the bracket in terms of inner products while we're at it

$$-i\delta_3 (2\pi)^D \delta(k - k')[(k \cdot k')(\varepsilon \cdot \varepsilon') - (k \cdot \varepsilon)(k' \cdot \varepsilon')]. \tag{4.3.22}$$

As before to get the Feynman rule we strip of terms corresponding to external legs and the momentum conservation Dirac delta, setting $k = k'$, to get the Feynman rule

$$\mu \;\xrightarrow{k}\!\!\otimes\!\!\xrightarrow{k}\; \nu \;=\; -i\delta_3(k^2 \eta_{\mu\nu} - k_\mu k_\nu). \tag{4.3.23}$$

Notice that we have to include the metric from $\varepsilon' \cdot \varepsilon = \eta_{\mu\nu}\varepsilon'^\mu \varepsilon^\nu$ in order for the indices to match up.

4.3.3 $\bar{\psi}A\!\!\!/\psi$ Term

The final counterterm to compute is the one from the $\bar{\psi}A\!\!\!/\psi$ term. The corresponding action is

$$S_{\text{int}} = \int d^D x [e\mu^\varepsilon \delta_1 \bar{\psi}A\!\!\!/\psi]. \tag{4.3.24}$$

This has three fields, so contributes as a three point vertex. To compute the counterterm in this case we consider the correlator $\langle \bar{\psi}(x_1)\psi(x_2)A^\mu(x_3)\rangle$. Expanding the exponential to first order in the interaction we want to compute

$$\int \mathcal{D}A \, \mathcal{D}\psi \, \mathcal{D}\bar{\psi} \, \bar{\psi}(x_1)\psi(x_2)A^\mu(x_3) \int d^D x \, e\mu^\varepsilon \delta_1 \bar{\psi}(x)A\!\!\!/^\nu(x)\psi(x) e^{iS[\psi,\bar{\psi},A]} \tag{4.3.25}$$

where $S[\psi, \bar{\psi}, A]$ is the free action. There is only one contraction not giving zero:

$$\int \mathcal{D}A \, \mathcal{D}\psi \, \mathcal{D}\bar{\psi} \, \overbrace{\bar{\psi}(x_1)\psi(x_2)A^\mu(x_3) \int d^D x \, e\mu^\varepsilon \delta_1 \bar{\psi}(x)A\!\!\!/^\nu(x)\psi(x)} e^{iS[\psi,\bar{\psi},A]}. \tag{4.3.26}$$

Computing the contractions we are left with external propagators, which we can drop, and then we get the amputated correlator $ie\mu^\varepsilon \delta_1 \gamma^\mu$. This gives the Feynman rule

 $\mu \;=\; ie\delta_1 \gamma^\mu \mu^\varepsilon \tag{4.3.27}$

4.4 Vacuum Polarisation

In this section we will compute the vacuum polarisation, which is a correction to an internal photon propagator. Before we proceed we'll recap the Feynman rules for QED, including the two counterterms we've just computed.

- The **QED vertex**:

$$\mu \;\rightsquigarrow\!\!\!\!\!< \quad = ie\mu^{\varepsilon}\gamma^{\mu}. \tag{4.4.1}$$

  Note the factor of μ^{ε} which we had not previously included as at tree level we were taking $\varepsilon = 0$.

- The QED propagators:

  - **Electron propagator**:

$$\xrightarrow{\;p\;} \quad = \frac{i(\not{p} + m)}{p^2 - m^2 + i\varepsilon}. \tag{4.4.2}$$

  - **Photon propagator**:

$$\mu \;\overset{k}{\rightsquigarrow}\; \nu \;= \frac{-i}{k^2 + i\varepsilon}\left(\eta^{\mu\nu} - (1 - \xi)\frac{k^{\mu}k^{\nu}}{k^2}\right). \tag{4.4.3}$$

    Here ξ is a gauge parameter. The choice of $\xi = 1$ is the **Feynman gauge**, giving the propagator

$$\frac{-i\eta_{\mu\nu}}{k^2 + i\varepsilon}, \tag{4.4.4}$$

    which is nice since the second term vanishes. The choice of $\xi = 0$ is the **Landau gauge** or **Lorenz gauge**, giving the propagator

$$\frac{i}{k^2 + i\varepsilon}\left(\eta^{\mu\nu} - \frac{k^{\mu}k^{\nu}}{k^2}\right), \tag{4.4.5}$$

    which is nice because when we multiply by k_{μ} this vanishes.

- Conserve momentum at each vertex.

- Integrate over internal momenta which aren't fixed by momentum conservation, giving an integral

$$\int \hat{\mathrm{d}}^D\ell = \int \frac{\mathrm{d}^D\ell}{(2\pi)}. \tag{4.4.6}$$

- Each closed fermion loop gives a factor of -1.

- Counterterms:

– electron counter term:

$$\xrightarrow{\;p\;}\otimes\xrightarrow{\;p\;} = i(\delta_2(\not{p} - m) + \delta m). \tag{4.4.7}$$

– photon counter term:

$$\mu \;\xrightarrow{\;k\;}\otimes\xrightarrow{\;k\;}\; \nu = -i\delta_3(k^2\eta_{\mu\nu} - k_\mu k_\nu). \tag{4.4.8}$$

- For an amputated correlator each external line simply gives a factor of 1.

Consider the correlator

$$\langle A_\mu(x)A_\nu(y)\rangle = \int \mathcal{D}A\,\mathcal{D}\psi\,\mathcal{D}\bar{\psi}\,A_\mu(x)A_\nu(y)\mathrm{e}^{iS}. \tag{4.4.9}$$

At order e^0 there is no interaction so the photon just propagates freely giving

$$\langle A_\mu(x)A_\nu(y)\rangle_{\mathcal{O}(e^0)} = iD_{\mu\nu}(x - y) \tag{4.4.10}$$

where $D_{\mu\nu}$ is the free photon propagator.

At order e^1 if we expand e^{iS} to get $1 + \mathcal{O}(e)$ we get three A fields and two ψ fields with no way to contract them all. This means that there is no $\mathcal{O}(e)$ contribution.

At order e^2 expanding e^{iS} we get

$$\int \mathcal{D}A\,\mathcal{D}\psi\,\mathcal{D}\bar{\psi}\,A_\mu(x)A_\nu(y)\frac{(ie)^2}{2}\int \mathrm{d}^D x_1\,\mathrm{d}^D x_2\,(\bar{\psi}\!\!\not{A}\psi)_{x_1}(\bar{\psi}\!\!\not{A}\psi)_{x_2} + \text{counterterm} \tag{4.4.11}$$

where $(-)_x$ means that all the fields in the brackets are evaluated at x. Diagrammatically this is

$$\mu\,\underset{}{\sim\!\!\!\sim}\,\bigcirc\,\underset{}{\sim\!\!\!\sim}\,\nu + \mu\,\underset{}{\sim\!\!\!\sim}\,\otimes\,\underset{}{\sim\!\!\!\sim}\,\nu\;. \tag{4.4.12}$$

The interesting part of the correlator is the loop, so define

$$i\Pi_{\mu\nu}(x - y) \coloneqq \langle A_\mu(x)A_\nu(y)\rangle|_{1\,\text{loop, amputated}} \tag{4.4.13}$$

to be just the loop without the counter term or external photon propagators. We want to work in momentum space so define

$$\widetilde{\Pi}_{\mu\nu}(k) = \int \mathrm{d}^D x\,\mathrm{e}^{ik\cdot x}\Pi_{\mu\nu}(x). \tag{4.4.14}$$

Then, enforcing momentum conservation, we have

$$i\widetilde{\Pi}_{\mu\nu}(k) = \;\mu\,\underset{k}{\sim\!\!\!\sim}\,\overset{q}{\bigcirc}\,\underset{k}{\underset{q-k}{\sim\!\!\!\sim}}\,\nu + \mu\,\underset{k}{\sim\!\!\!\sim}\,\otimes\,\underset{k}{\sim\!\!\!\sim}\,\nu\;. \tag{4.4.15}$$

To evaluate this we use the Feynman rules, which give

- A factor of -1 from the fermion loop.

- An integral $\int \hat{\mathrm{d}}^D q$ for the undetermined momentum.

- Entering on the left we first come to a photon propagator, but this is external and we're considering an amputated correlator so it gives a factor of 1.

- Next we reach a QED vertex giving a factor of $ie\mu^\varepsilon\gamma^\mu$.

- We then proceed *backwards* along the fermion line, which is an electron propagator with momentum $q - k$, giving a factor of

$$\frac{i(q\!\!\!/ - k\!\!\!/ + m)}{(q - k)^2 - m^2 + i\varepsilon}. \tag{4.4.16}$$

- Another QED vertex giving a factor of $ie\mu^\varepsilon\gamma^\nu$.

- Continuing backwards along the fermion propagator with momentum q we get

$$\frac{i(q\!\!\!/ + m)}{q^2 - m^2 + i\varepsilon}. \tag{4.4.17}$$

Call these electron propagators $S(q - k)$ and $S(q)$ and write in the spinor indices. We then have a factor of

$$\gamma^\mu_{ab} S_{bc}(q - k)\gamma^\nu_{cd} S_{da}(q) = S_{da}(q)\gamma^\mu_{ab} S_{bc}(q - k)\gamma^\nu_{cd} \tag{4.4.18}$$

$$= \mathrm{tr}(S(q)\gamma^\mu S(q - k)\gamma^\nu) \tag{4.4.19}$$

$$= \mathrm{tr}(\gamma^\mu S(q - k)\gamma^\nu S(q)). \tag{4.4.20}$$

Putting this all together we get

$$-\int \hat{\mathrm{d}}^D q (ie\mu^\varepsilon)^2 \, \mathrm{tr}\left[\gamma^\mu \frac{i(q\!\!\!/ - k\!\!\!/ + m)}{(q - k)^2 - m^2 + i\varepsilon}\gamma^\nu \frac{i(q\!\!\!/ + m)}{q^2 - m^2 + i\varepsilon}\right] - i\delta_3(k^2\eta^{\mu\nu} - k^\mu k^\nu).$$

Five

Evaluating Loop Integrals

One loop integrals can be computed using the following algorithm[1]

1. Use Feynman parametrisation to rewrite the denominators. The simple case is

$$\frac{1}{AB} = \int_0^1 dx \, \frac{1}{[xA + (1-x)B]^2} \tag{5.0.1}$$

and the more general case is

$$\frac{1}{A^{\alpha_1} \cdots A^{\alpha_n}} = \int_0^1 dx_1 \, x^{\alpha_1 - 1} \cdots \int_0^1 dx_n \, x^{\alpha_n - 1}$$
$$\times \frac{\delta(1 - \sum_i \alpha_i)}{[\alpha_1 A_1 + \cdots + \alpha_n A_n]^{\sum_i \alpha_i}} \frac{\Gamma(\sum_i \alpha_i)}{\Gamma(\alpha_1) \cdots \Gamma(\alpha_n)}.$$

2. Shift the loop momentum to get the integral in the form

$$\int \hat{d}^D \ell \, \frac{N}{(\ell^2 - \Delta)^n}. \tag{5.0.2}$$

3. Simplify the numerator. This step is new to QED since for scalar φ^3 theory as seen in *Quantum Field Theory* the numerator is always one. We'll see several tricks for performing this simplification later.

4. Wick rotate defining $\ell^0 = i\ell_E^0$ and $\ell^2 = -(\ell_E)^2 - \ell^2 = -\ell_E^2$ where ℓ_E^2 is the Euclidean inner product, $\ell_E^2 = \ell_E^2 + \ell^2$.

5. Use the identity

$$\int \hat{d}^D \ell_E \, \frac{(\ell_E^2)^p}{(\ell_E + \Delta)^n} = \frac{\Gamma(n - p - D/2)\Gamma(p + D/2)}{(4\pi)^{D/2}\Gamma(n)\Gamma(D/2)} \Delta^{D/2 + p - n}. \tag{5.0.3}$$

We can combine the fourth and fifth steps into one to get the identity

$$\int \hat{d}^D \ell \, \frac{(\ell^2)^p}{(\ell^2 - \Delta)^n} = \frac{i}{(4\pi)^{D/2}} \frac{(-1)^{p+n}\Gamma(n - p - D/2)\Gamma(p + D/2)}{\Gamma(n)\Gamma(D/2)} \Delta^{p/2 + p - n}.$$

Note that the Δ term can be found from dimensional analysis. We know from the $\ell^2 - \Delta$ term that[2] $[\Delta] = 2$. Then looking at the integral on the left we have

$[\hat{\mathrm{d}}^D \ell] = D$, $[(\ell^2)^p] = 2p$, and $[(\ell^2 - \Delta)^n] = 2n$, so the integral has mass dimension $D + 2p - 2n$. Dimensions can only enter the right hand side as Δ^x, since we are integrating out ℓ, so we must have $[\Delta^x] = 2x = D + 2p - 2n$, so $x = D/2 + p - n$.

In QED we often encounter **tensor integrals** such as

$$I^{\mu_1 \cdots \mu_r} := \int \hat{\mathrm{d}}^D \ell \frac{\ell^{\mu_1} \cdots \ell^{\mu_r}}{(\ell^2 - \Delta)^n}. \tag{5.0.4}$$

First consider the $r = 1$ case:

$$I^\mu = \int \hat{\mathrm{d}}^D \ell \frac{\ell^\mu}{(\ell^2 - \Delta)^n}. \tag{5.0.5}$$

A change of variables from ℓ to $-\ell$ gives an overall negative from $\mathrm{d}\ell \to -\mathrm{d}\ell$ as well as exchanging the limits from $(-\infty, \infty)$ to $(\infty, -\infty)$. We can change the limits back at the cost of another overall negative. We also get an overall negative from $\ell^\mu \to \ell^\mu$ so

$$I^\mu = \int \hat{\mathrm{d}}^D \ell \frac{-\ell^\mu}{(\ell^2 - \Delta)^n} = -I^\mu \tag{5.0.6}$$

and so we must have $I^\mu = 0$. This same logic can be applied whenever r is odd, so $I^{\mu_1 \cdots \mu_r} = 0$ for all odd r.

Now consider the $r = 2$ case:

$$I^{\mu\nu} = \int \hat{\mathrm{d}}^D \ell \frac{\ell^\mu \ell^\nu}{(\ell^2 - \Delta)^n}. \tag{5.0.7}$$

The result must also be a rank two tensor. Since we are integrating over ℓ the result can only depend on Δ, which is just a scalar. The only other dependence in this integral is on the metric, $\eta^{\mu\nu}$, so this must be where the indices come from. We make the ansatz that

$$I^{\mu\nu} = \eta^{\mu\nu} X(\Delta) \tag{5.0.8}$$

where X is some function to be determined. Now notice that

$$\eta_{\mu\nu} I^{\mu\nu} = I^\mu{}_\mu = \eta_{\mu\nu} \eta^{\mu\nu} X(\Delta) = D X(\Delta) = \int \hat{\mathrm{d}}^D \ell \frac{\ell^2}{(\ell^2 - \Delta)^n}, \tag{5.0.9}$$

and we know what this result integral is so we have

$$I^{\mu\nu} = \frac{1}{D} \int \hat{\mathrm{d}}^D \ell \frac{\eta^{\mu\nu} \ell^2}{(\ell^2 - \Delta)^n}. \tag{5.0.10}$$

To conclude, in a loop integral we can replace $\ell^\mu \ell^\nu$ with $\eta^{\mu\nu} \ell^2 / D$ so long as the denominator is of the form $(\ell^2 - \Delta)^n$. Other even r cases can be worked out in a similar manor.

5.1 Vacuum Polarisation

Let's return to the problem of computing the vacuum polarisation. Define a function corresponding to just the loop part of the vacuum polarisation:

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = \quad \mu \underset{\longrightarrow}{\wwwwww} \underset{k}{\bigcirc} \underset{\longrightarrow}{\wwwwww} \nu \quad . \tag{5.1.1}$$

As we computed before using the Feynman rules gives the result

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = -(ie\mu^{\varepsilon})^2 \int \mathrm{d}^D q \frac{\mathrm{tr}[\gamma^{\mu} i(\slashed{q} - \slashed{k} + m)\gamma^{\nu} i(\slashed{q} + m)]}{[(q-k)^2 - m^2 + i\varepsilon][q^2 - m^2 + i\varepsilon]}. \tag{5.1.2}$$

The first step of the algorithm is to use Feynman parametrisation. In this case we have two denominators, $(q-k)^2 - m^2 + i\varepsilon$ and $q^2 - m^2 + i\varepsilon$. We have to decide which one goes with x and which goes with $1-x$ in

$$\frac{1}{AB} = \int_0^1 \mathrm{d}x \frac{1}{[xA + (1-x)B]^2}. \tag{5.1.3}$$

A good idea is to put the more complicated factor with x, so that we don't increase the complexity. This gives

$$A = x[(q-k)^2 - m^2 + i\varepsilon] = xq^2 - 2xq \cdot k + xk^2 - xm^2 + ix\varepsilon, \tag{5.1.4}$$
$$B = (1-x)[q^2 - m^2 + i\varepsilon] = q^2 - xq^2 - m^2 + xm^2 + i\varepsilon - ix\varepsilon. \tag{5.1.5}$$

Hence, we have

$$xA + (1-x)B = q^2 - 2xq \cdot k + xk^2 - m^2 + i\varepsilon. \tag{5.1.6}$$

This allows us to rewrite the loop integral as

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = e^2\mu^{2\varepsilon} \int_0^1 \mathrm{d}x \int \mathrm{d}^D q \frac{\mathrm{tr}[(\gamma^{\mu}(\slashed{q} - \slashed{k} + m)\gamma^{\nu}(\slashed{q} + m))]}{q^2 - 2xq \cdot k + xk^2 - m^2 + i\varepsilon}. \tag{5.1.7}$$

The next step of the algorithm is to shift the integration variable to get a denominator of the form $(\ell^2 - \Delta)^n$. To do this we choose $\ell = q - xk$, then we have $\ell^2 = q^2 - 2xq \cdot k + x^2k^2$ and so

$$q^2 - 2xq \cdot k + xk^2 - m^2 + i\varepsilon = \ell^2 - m^2 + x(1-x)k^2 + i\varepsilon = \ell^2 - \Delta \tag{5.1.8}$$

with

$$\Delta := m^2 - x(1-x)k^2 - i\varepsilon. \tag{5.1.9}$$

Then the loop integral is

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = -e^2\mu^{2\varepsilon} \int_0^1 \mathrm{d}x \int \mathrm{d}^D \ell \frac{N^{\mu\nu}}{(\ell^2 - \Delta)^2} \tag{5.1.10}$$

with

$$N^{\mu\nu} = \mathrm{tr}[\gamma^{\mu}(\slashed{q} - \slashed{k} + m)\gamma^{\nu}(\slashed{q} + m)]. \tag{5.1.11}$$

The next step in the algorithm is to simplify the numerator. The first step is to write the numerator in terms of ℓ which can be done by inverting $\ell = q - xk$ to get $q = \ell + xk$. We also have $q - k = \ell + xk - k = \ell - (1-x)k$. Thus the numerator is

$$N^{\mu\nu} = \mathrm{tr}[\gamma^{\mu}(\slashed{\ell} - (1-x)\slashed{k} + m)\gamma^{\nu}(\slashed{\ell} + x\slashed{k} + m)]. \tag{5.1.12}$$

We can now expand the product in the trace. In doing so we keep only terms with an even power of gamma matrices, since the trace of an odd number of gamma matrices vanishes. We also keep only terms with an even power of ℓ, since under the integral any odd power of ℓ vanishes. Note that this is only true under the integral, not in general, so rather than using equality we'll use the symbol $\rightsquigarrow$:

$$N^{\mu\nu} \rightsquigarrow \text{tr}[\gamma^\mu \ell \gamma^\nu \ell - x(1-x)\gamma^\mu k \gamma^\nu k + m^2 \gamma^\mu \gamma^\nu]. \tag{5.1.13}$$

To proceed we need the following two identities for traces of gamma matrices:

$$\text{tr}[\gamma^\mu \gamma^\nu] = 4\eta^{\mu\nu}, \tag{5.1.14}$$

$$\text{tr}[\gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma] = 4(\eta^{\mu\nu}\eta^{\rho\sigma} + \eta^{\sigma\mu}\eta^{\nu\rho} - \eta^{\mu\rho}\eta^{\nu\sigma}). \tag{5.1.15}$$

Note that the factor of 4 is the dimension of the spinors. It is possible to define the spinors in such a way that they are four component objects even in dimensional regularisation where the spacetime dimension is $D = 4 - 2\varepsilon$. Consider the first term in the trace, we have

$$\text{tr}[\gamma^\mu \ell \gamma^\nu \ell] = \ell_\rho \ell_\sigma \, \text{tr}[\gamma^\mu \gamma^\rho \gamma^\nu \gamma^\sigma] \tag{5.1.16}$$

$$= 4\ell_\rho \ell_\sigma [\eta^{\mu\rho}\eta^{\nu\sigma} + \eta^{\rho\nu}\eta^{\sigma\mu} - \eta^{\mu\nu}\eta^{\rho\sigma}] \tag{5.1.17}$$

$$= 4[\ell^\mu \ell^\nu + \ell^\nu \ell^\mu - \eta^{\mu\nu}\ell^2] \tag{5.1.18}$$

$$= 4[2\ell^\mu \ell^\nu - \eta^{\mu\nu}\ell^2]. \tag{5.1.19}$$

In general in traces like this if we have $\gamma^\mu \ell$ then we the index μ in the identity for traces of $\gamma^\mu \gamma^\nu$ will be attached to the ℓ in the final result. The second term in the numerator is the same but with ks in place of the ℓs, and an extra scalar factor. The last term in the trace is simply $4m^2 \eta^{\mu\nu}$. Combined we have

$$N^{\mu\nu} \rightsquigarrow 4[2\ell^\mu \ell^\nu - \eta^{\mu\nu}\ell^2 - x(1-x)(2k^\mu k^\nu - \eta^{\mu\nu}k^2) + m^2\eta^{\mu\nu}]. \tag{5.1.20}$$

We can further simplify this by using $\Delta = m^2 - x(1-x)k^2 - i\varepsilon$ and so $m^2 = \Delta + x(1-x)k^2 + i\varepsilon$ giving

$$N^{\mu\nu} \rightsquigarrow 4[2\ell^\mu \ell^\nu - \eta^{\mu\nu}\ell^2 - 2x(1-x)(k^\mu k^\nu - \eta^{\mu\nu}k^2) + \Delta\eta^{\mu\nu}]. \tag{5.1.21}$$

The final simplification we can make is to use our earlier discovery that we can replace $\ell^\mu \ell^\nu$ with $\eta^{\mu\nu}\ell^2/D$ under a one loop integral with denominator $(\ell^2 - \Delta)^n$. This gives

$$N^{\mu\nu} \rightsquigarrow 4\left[\frac{2}{D}\eta^{\mu\nu}\ell^2 - \eta^{\mu\nu}\ell^2 - 2x(1-x)(k^\mu k^\nu - \eta^{\mu\nu}k^2) + \Delta\eta^{\mu\nu}\right] \tag{5.1.22}$$

$$= 4\left[\left(\frac{2}{D} - 1\right)\eta^{\mu\nu}\ell^2 - 2x(1-x)(k^\mu k^\nu - \eta^{\mu\nu}) + \Delta\eta^{\mu\nu}\right]. \tag{5.1.23}$$

We can now use the two following integrals, first

$$\int \hat{\text{d}}^D \ell \frac{1}{(\ell^2 - \Delta)^2} = \frac{i}{(4\pi)^{D/2}} \Delta^{D/2-2} \Gamma(2 - D/2) \tag{5.1.24}$$

which follows by setting $p = 0$ and $n = 2$ in the general formula and using $\Gamma(1) = 1$. Second, we need

$$\int \hat{\text{d}}^D \ell \frac{\ell^2}{(\ell^2 - \Delta)^2} = -\frac{i}{(4\pi)^{D/2}} \Delta^{D/2-1} \frac{\Gamma(1 - D/2)\Gamma(1 + D/2)}{\Gamma(D/2)}. \tag{5.1.25}$$

This can be simplified using the identity $\Gamma(1+z) = z\Gamma(z)$, which is just the factorial recursive definition extended to the Γ function. With this we have

$$\Gamma(1 + D/2) = \frac{D}{2}\Gamma(D/2) \tag{5.1.26}$$

and so

$$\int \hat{\mathrm{d}}^D \ell \frac{\ell^2}{(\ell^2 - \Delta)^2} = -\frac{i}{(4\pi)^{D/2}} \Delta^{D/2-1} \frac{D}{2} \Gamma(1 - D/2). \tag{5.1.27}$$

Using these integrals for each term of the full integral we get the result

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = -4e^2\mu^{2\varepsilon} \int_0^1 \mathrm{d}x \frac{i}{(4\pi)^{D/2}} \tag{5.1.28}$$
$$\times \left[\frac{D}{2}\left(\frac{2}{D} - 1\right)\Gamma(1 - D/2)\Delta^{D/2-1}\eta^{\mu\nu} \right.$$
$$- 2x(1-x)\Gamma(2 - D/2)\Delta^{D/2-2}(k^\mu k^\nu - \eta^{\mu\nu}k^2)$$
$$\left. + \Gamma(2 - D/2)\Delta^{D/2-1}\eta^{\mu\nu} \right].$$

Now we can use

$$\frac{D}{2}\left(\frac{2}{D} - 1\right)\Gamma(1 - D/2) = \left(1 - \frac{D}{2}\right)\Gamma(1 - D/2) = \Gamma(2 - D/2), \tag{5.1.29}$$

which is just another application of $z\Gamma(z) = \Gamma(1 + z)$. Doing this the first and last term above are the same and so cancel out giving the final result

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = \frac{8e^2\mu^{2\varepsilon}}{(4\pi)^{D/2}}(k^\mu k^\nu - \eta^{\mu\nu}k^2)\Gamma(2 - D/2) \int_0^1 \mathrm{d}x\, x(1-x)\Delta^{D/2-2}. \tag{5.1.30}$$

Note that Δ depends on x so we can't pull it outside of the integral.

5.1.1 Regularisation

We will use dimensional regularisation, setting the number of dimensions to $D = 4 - 2\varepsilon$ for some $\varepsilon \in \mathbb{R}$ which we will later take to zero. This means that we can neglect terms on the order of ε, although these terms may be important for two loop diagrams. We keep the poles, terms like $1/\varepsilon$, and finite[3] terms, $\mathcal{O}(\varepsilon^0)$.

[3] finite here meaning finite and nonzero

The gamma function appearing in the vacuum polarisation loop becomes

$$\Gamma(2 - D/2) = \Gamma(\varepsilon). \tag{5.1.31}$$

We can then use the expansion of the gamma function about zero:

$$\Gamma(\varepsilon) \approx \frac{1}{\varepsilon} - \gamma + \mathcal{O}(\varepsilon) \tag{5.1.32}$$

where

$$\gamma \approx 0.57721566 \tag{5.1.33}$$

is the **Euler–Mascheroni constant**. It is actually more useful to write this expansion as

$$\frac{1}{\varepsilon}\mathrm{e}^{-\varepsilon\gamma} + \mathcal{O}(\varepsilon) \approx \frac{1}{\varepsilon}(1 - \varepsilon\gamma) + \mathcal{O}(\varepsilon) = \frac{1}{\varepsilon} - \gamma + \mathcal{O}(\varepsilon) \approx \Gamma(\varepsilon). \tag{5.1.34}$$

Using this, and factoring out a minus sign from the tensor structure, we can write the vacuum polarisation loop as

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = -\frac{8ie^2}{16\pi^2}(4\pi\mu^2\mathrm{e}^{-\gamma})^\varepsilon(k^2\eta^{\mu\nu} - k^\mu k^\nu)\frac{1}{\varepsilon}\int_0^1 \mathrm{d}x\, x(1-x)\Delta^{-\varepsilon}. \quad (5.1.35)$$

The integral here is over a finite region, $[0, 1]$, and so diverges only if the integrand diverges. In dimensional regularisation we always get factors of $4\pi\mu^2\mathrm{e}^{-\gamma}$, so it helps to define

$$\tilde{\mu}^2 = 4\pi\mu^2\mathrm{e}^{-\gamma} \approx 7.0555\mu^2. \quad (5.1.36)$$

Now write

$$\tilde{\mu}^{2\varepsilon}\Delta^{-\varepsilon} = \left(\frac{\Delta}{\tilde{\mu}^2}\right)^{-\varepsilon} \quad (5.1.37)$$

$$= \exp\left\{\log\left(\frac{\Delta}{\tilde{\mu}^2}\right)^{-\varepsilon}\right\} \quad (5.1.38)$$

$$= \exp\left\{-\varepsilon\log\frac{\Delta}{\tilde{\mu}^2}\right\} \quad (5.1.39)$$

$$\approx 1 - \varepsilon\log\frac{\Delta}{\tilde{\mu}^2} + \mathcal{O}(\varepsilon^2). \quad (5.1.40)$$

Then we have

$$i\widetilde{\Pi}_{\mathrm{L}}^{\mu\nu}(k) = -\frac{ie^2}{2\pi^2}(k^2\eta^{\mu\nu} - k^\mu k^\nu)\int_0^1 \mathrm{d}x\, x(1-x)\left[\frac{1}{\varepsilon} - \log\frac{\Delta}{\tilde{\mu}^2}\right]. \quad (5.1.41)$$

This is now perfectly finite so long as $\varepsilon \neq 0$ (and $\Delta/\tilde{\mu}^2 > 0$).

5.1.2 Renormalisation

We require that correlators of renormalised fields are finite. Recall that the counter term appearing in the vacuum polarisation is

$$\mu \overset{k}{\underset{}{\rightsquigarrow}}\otimes\overset{k}{\underset{}{\rightsquigarrow}} \nu \;\; = -i\delta_3(k^2\eta^{\mu\nu} - k^\mu k^\nu). \quad (5.1.42)$$

Fortunately this has the same tensor structure, $k^2\eta^{\mu\nu} - k^\mu k^\nu$, as the loop part of the vacuum polarisation. This is important as it allows us to choose δ_3 to cancel the infinities which occur in the loop integral to get a finite result. This is not always the case. For example, if we use an ultraviolet cut-off, Λ, then the cancellation earlier in the calculation doesn't occur and we don't have matching tensor structures. The reason for this is that dimensional regularisation respects gauge symmetry, but an ultraviolet cut-off doesn't, since, for example, a gauge transformation $p_\mu \mapsto p_\mu + eA_\mu$ could result in a momentum with $p^2 > \Lambda^2$.

We can write the full one-loop vacuum polarisation as

$$\widetilde{\Pi}^{\mu\nu}(k) = \ \raisebox{-1em}{[diagram]} \quad (5.1.43)$$

$$= (k^2\eta^{\mu\nu} - k^\mu k^\nu)\left[-\delta_3 - \frac{e^2}{2\pi^2}\int_0^1 dx\, x(1-x)\left[\frac{1}{\varepsilon} - \log\frac{\Delta}{\tilde{\mu}^2}\right]\right]. \quad (5.1.44)$$

We can compute the first term in the integral,

$$\frac{1}{\varepsilon}\int_0^1 dx\, x(1-x) = \frac{1}{6\varepsilon}, \quad (5.1.45)$$

giving

$$\widetilde{\Pi}^{\mu\nu}(k) = (k^2\eta^{\mu\nu} - k^\mu k^\nu)\left[-\delta_3 - \frac{e^2}{12\pi^2\varepsilon} - \frac{e^2}{2\pi^2}\int_0^1 dx\, x(1-x)\log\frac{\Delta}{\tilde{\mu}^2}\right] \quad (5.1.46)$$

$$= (k^2\eta^{\mu\nu} - k^\mu k^\nu)\Pi(k^2) \quad (5.1.47)$$

where we define $\Pi(k^2)$ to contain the scalar structure of the vacuum polarisation.

We demand that this scalar structure is finite, however currently we have a pole at $\varepsilon = 0$ from the $1/\varepsilon$ term. The solution is to choose δ_3 to be of the form

$$\delta_3 = -\frac{e^2}{12\pi^2\varepsilon} + \text{finite terms} \quad (5.1.48)$$

so that the $1/\varepsilon$ terms cancel out and we are left only with the finite terms.

5.1.2.1 Choice of Renormalisation Scheme

Clearly in the above prescription for δ_3 we have some freedom in the choice of finite terms. In general we can add terms $\mathcal{O}(\varepsilon^0)$ to δ_3 and the result will still be finite. This freedom is the freedom in choosing a **renormalisation scheme**. We'll discuss two renormalisation schemes here.

$\overline{\text{MS}}$ *Scheme.* The $\overline{\text{MS}}$ scheme, standing for **modified minimal subtraction**, is defined by two requirements:

• We use

$$\tilde{\mu}^2 = 4\pi\mu^2 e^{-\gamma} \quad (5.1.49)$$

as a parameter. This is the "modified" part of modified minimal subtraction, and simply reduces the number of 4πs and $e^{-\gamma}$s that we have to deal with.

• We require counterterms to contain only poles, so no finite terms, this is the "minimal subtraction" part of modified minimal subtraction. This means that all counterterms are of the form

$$\delta_i = \sum_{n=1}^{\infty}\frac{a_n}{\varepsilon^n} \quad (5.1.50)$$

for some finite quantities a_n.

Thus in $\overline{\text{MS}}$ the counterterm for the vacuum polarisation term is

$$\delta_3 = \frac{e^2}{12\pi^2\varepsilon} + \mathcal{O}\left(\frac{e^4}{\varepsilon^2}\right). \tag{5.1.51}$$

The factor in front of any higher order term is just a number, it has no dependence on momentum, since it can be traced back to the Lagrangian where all momenta are explicitly accounted for.

We will almost entirely use the $\overline{\text{MS}}$ scheme, but it isn't the only choice. For the rest of this section we'll briefly discuss an alternative.

On-shell Scheme. The **on-shell scheme** is imposed by the normalisation condition $\Pi(0) = 0$. If we write out $\Pi(k^2)$ in full[4],

[4]we use ε here for the parameter of dimensional regularisation and ϵ for the parameter of the $i\epsilon$ prescription.

$$\Pi(k^2) = -\left[\delta_3 + \frac{e^2}{12\pi^2\varepsilon} - \frac{e^2}{2\pi^2}\int_0^1 \mathrm{d}x\, x(1-x)\log\left(\frac{m^2 - x(1-x)k^2 - i\epsilon}{\tilde{\mu}^2}\right)\right] \tag{5.1.52}$$

then we see that at $k^2 = 0$ we can take $\epsilon \to 0$ since $m^2 > 0$. The integral is then easy to do, again giving 1/6, and so

$$\Pi(0) = -\left[\delta_3 + \frac{e^2}{12\pi^2\varepsilon} - \frac{e^2}{12\pi^2}\log\frac{m^2}{\tilde{\mu}^2}\right]. \tag{5.1.53}$$
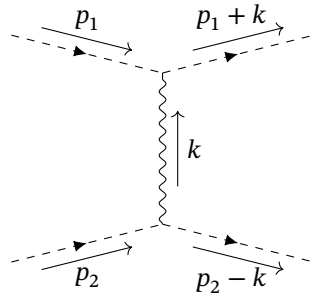

Demanding $\Pi(0) = 0$ we get

$$\delta_3 = -\frac{e^2}{12\pi^2\varepsilon} + \frac{e^2}{12\pi^2}\log\frac{m^2}{\tilde{\mu}^2}. \tag{5.1.54}$$

A sensible question is why we impose $\Pi(0) = 0$ as a condition. There are at least two reasons for this. First, doing so ensures that the photon propagator takes on its tree form,

$$\frac{i\eta^{\mu\nu}}{k^2 + i\epsilon}. \tag{5.1.55}$$

Essentially, this means that the photon remains massless, since the propagator has a pole at the physical mass.

The second reason can be demonstrated by considering $2 \to 2$ scattering. For simplicity we'll consider scalars scattering, which just allows us to drop the spinors that would normally occur. Consider the process

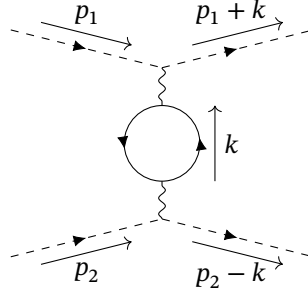

$$\tag{5.1.56}$$

The amplitude for this at tree level is

$$i\mathcal{A}_{\text{tree}} = \frac{ie^2}{k^2}(4p_1 \cdot p_2 - k^2). \tag{5.1.57}$$

At large distances k^2 is small, so

$$i\mathcal{A}_{\text{tree}} \approx \frac{ie^2}{k^2}4p_1 \cdot p_2. \tag{5.1.58}$$

At one loop we encounter diagrams like

In fact, we can carefully choose our theory so that this is the dominant diagram at one-loop. Diagrams such as

are suppressed by powers of $1/m$, with m the mass of the external particles. By choosing a theory with lots of fermions we can also make the fermion loop the dominant loop.

Notice that the diagram contains the loop diagram in the vacuum polarisation as a subdiagram. This means that we can just replace the normal photon propagator with this term, which we've already computed. This gives

$$i\mathcal{A}_{\text{loop}} = (ie)^2(2p_1 + k)^\mu(2p_2 - k)^\nu\left(-\frac{i}{k^2}\right)(k^2\eta_{\mu\nu} - k_\mu k_\nu)\Pi(k^2) \tag{5.1.61}$$

$$= (ie)^2 4(k^2(p_1 \cdot p_2) - (p_1 \cdot k)(p_2 \cdot k))\frac{1}{k^4}\Pi(k^2) \tag{5.1.62}$$

where in the second line we've used $k^\mu(k^2\eta_{\mu\nu} - k_\mu k_\nu) = 0$. At large distances we then have

$$i(\mathcal{A}_{\text{tree}} + \mathcal{A}_{\text{loop}}) \approx \frac{i}{k^2}4p_1 \cdot p_2 e^2(1 + \Pi(k^2)). \tag{5.1.63}$$

One way to measure the charge of a particle is to perform scattering experiments like this one. These are typically done at low momentum. What we actually measure in these experiments is the factor $e^2(1+\Pi(k^2))$, plus any higher order corrections. Choosing $\Pi(0) = 0$ then means that the value we are measuring is the renormalised charge, which is the charge appearing in the Lagrangian after regularisation.

Six

Interpreting The Vacuum Polarisation

Recall that in the last chapter we computed the vacuum polarisation

$$\Pi^{\mu\nu}(k) = \overset{q}{\underset{q-k}{\mu \;\;\;\;\;\; \nu}} + \overset{\mu \;\;\; \nu}{\underset{k \;\;\; k}{}} \tag{6.0.1}$$

$$= (k^{\mu}k^{\nu} - \eta k^2)\Pi(k^2) \tag{6.0.2}$$

where

$$\Pi(k^2) = \begin{cases} \dfrac{e^2}{2\pi^2} \displaystyle\int_0^1 \mathrm{d}x\, x(1-x) \log \dfrac{\Delta}{\tilde{\mu}^2} & \overline{\text{MS}}, \\[4mm] \dfrac{e^2}{2\pi^2} \displaystyle\int_0^1 \mathrm{d}x\, x(1-x) \log \dfrac{\Delta}{m^2} & \text{on-shell}, \end{cases} \tag{6.0.3}$$

where

$$\Delta = m^2 - x(1-x)k^2 - i\varepsilon. \tag{6.0.4}$$

Now we're going to try to extract some physics from this result and discuss the effects of the two different renormalisation scales.

6.1 Scale Dependence of Charge

Previously (Equation (5.1.63)) we saw that the amplitude for $2 \to 2$ scattering process between scalar particles exchanging a photon has

$$i\mathcal{A} = \frac{4i}{k^2} p_1 \cdot p_2 e^2 (1 + \Pi(k^2)). \tag{6.1.1}$$

This includes the tree level process and a single fermion loop in the photon propagator, and it is assumed that k^2 is small.

We can use this process to measure the charge of the particle in scattering process with zero, or very little, momentum. We find that measured charge squared,

at one loop accuracy, is then

$$e_{\text{meas}}^2 = e^2(1 + \Pi(0)) \tag{6.1.2}$$

$$= \begin{cases} e^2 \left(1 + \dfrac{e^2}{12\pi^2} \log \dfrac{m^2}{\tilde{\mu}^2}\right) & \overline{\text{MS}}, \\ e^2 & \text{on-shell.} \end{cases} \tag{6.1.3}$$

We can see that the relation between the Lagrangian parameters and the physical observables is scheme dependent. This isn't too much of a problem because in QED we can make a finite number of measurements to determine these parameters and from there we can use them to make scheme independent predictions.

For example, at nonzero momentum there is a correction to the measured charge squared:

$$e_{\text{meas}}^2(k^2) - e_{\text{meas}}^2(0) = e^2(1 + \Pi(k^2)) - e^2(1 + \Pi(0)) \tag{6.1.4}$$

$$= e^2(\Pi(k^2) - \Pi(0)) \tag{6.1.5}$$

$$= \frac{e^4}{2\pi^2} \int_0^1 \mathrm{d}x\, x(1-x) \log \frac{\Delta}{m^2} \tag{6.1.6}$$

in the $\overline{\text{MS}}$ scheme. This $\mathcal{O}(e^4)$ correction to the measured charge is a physical prediction of QED.

6.2 Non-Relativistic Limit

We can take the non-relativistic limit in QFT to compare results to results from non-relativistic quantum mechanics. Recall that in quantum mechanics the Born approximation gives the scattering amplitude

$$\mathcal{A} = -4m_1 m_2 \int \mathrm{d}^3 x\, \mathrm{e}^{-i\boldsymbol{k}\cdot\boldsymbol{x}} V(\boldsymbol{x}) \tag{6.2.1}$$

where m_i are the masses of the two particles scattering and $V(\boldsymbol{x})$ is the potential they are scattering in, with $\boldsymbol{x}$ being the vector between the two particles.

Note that this differs by a factor of $2m$ from the amplitudes we have been calculating. This is due to a difference in normalisation, where in quantum mechanics

$$\langle \boldsymbol{p} | \boldsymbol{p}' \rangle = \delta(\boldsymbol{p} - \boldsymbol{p}') \tag{6.2.2}$$

and in QFT

$$\langle p | p' \rangle = \frac{1}{2E_p} \delta(p - p') \tag{6.2.3}$$

with $2E_p \approx 2m$ in the non-relativistic limit.

Consider Coulomb scattering, the amplitude calculated in quantum mechanics is then

$$\mathcal{A} = -4m_1 m_2 \int \mathrm{d}^3 x\, \mathrm{e}^{-i\boldsymbol{k}\cdot\boldsymbol{x}} \frac{e_1 e_2}{4\pi|\boldsymbol{x}|} \tag{6.2.4}$$

$$= -4m_1 m_2 \frac{e_1 e_2}{|\boldsymbol{k}|^2}. \tag{6.2.5}$$

For the non-relativistic QFT result we take k^2 to be small. Note that $p_1 \cdot p_2 \approx m_1 m_2$. There is an incoming (and hence on-shell) particle with momentum p_1, so $p_1^2 = m_1^2$. There is an outgoing (and hence on-shell) particle with momentum $p_1 + k$, so

$$(p_1 + k)^2 = m_1^2 = m_1^2 + 2p_1 \cdot k + k^2. \tag{6.2.6}$$

From this, neglecting k^2 terms, we see that $2p_1 \cdot k \approx 0$. Since $p_1^0 \approx m_1$, which can be large, we must have $k^0 \approx 0$, and so $k^2 \approx -\boldsymbol{k}^2$. Then the amplitude calculated in QFT is

$$\mathcal{A} = -\frac{4m_1 m_2}{|\boldsymbol{k}|^2} e_1 e_2 (1 + \Pi(-\boldsymbol{k}^2)). \tag{6.2.7}$$

We can interpret this as having a one-loop correction to the potential, given in momentum space by

$$\Delta \tilde{V}(\boldsymbol{k}) = \frac{e_1 e_2}{\boldsymbol{k}^2} \Pi(-\boldsymbol{k}^2) \tag{6.2.8}$$

and in real space by

$$\Delta V(\boldsymbol{r}) = e_1 e_2 \int \hat{\mathrm{d}}^3 k \, \mathrm{e}^{-i\boldsymbol{k}\cdot\boldsymbol{r}} \frac{\Pi(-\boldsymbol{k}^2)}{\boldsymbol{k}^2}. \tag{6.2.9}$$

This corrected potential is called the **Uehling potential**.

In the on-shell scheme for $k^2 \ll m^2$ we can expand

$$\Pi(k^2) = \frac{e^2}{2\pi^2} \int_0^1 \mathrm{d}x \, x(1-x) \log\left(1 - x(1-x)\frac{k^2}{m^2}\right) \tag{6.2.10}$$

$$\approx \frac{e^2}{2\pi^2} \int_0^1 \mathrm{d}x \, x(1-x) \left[-x(1-x)\frac{k^2}{m^2}\right] \tag{6.2.11}$$

$$= \frac{e^2}{60\pi^2} \frac{\boldsymbol{k}^2}{m^2}. \tag{6.2.12}$$

Here we've used the expansion $\log(1 + \alpha) \approx \alpha$ and we've set $\epsilon = 0$ since the term in the logarithm is positive as $k^2 < m^2$ and $0 < x(1-x) < 1/4$.

Hence, the correction to the potential is

$$\Delta V(\boldsymbol{r}) = \frac{e_1 e_2 e^2}{60\pi^2 m^2} \delta(\boldsymbol{r}). \tag{6.2.13}$$

If we consider one of the particles to be a nucleus with Z protons then $e_1 = -Ze$, taking the other particle to be an electron, $e_2 = e$, we can interpret this as a shift in the energy levels of the atom. Note that since we're considering scalar particles scattering we are essentially ignoring spin-orbit effects, however these are subdominant terms since there is no direct spin-dependence in the potential. The energy shift is given by

$$\Delta E = \int \mathrm{d}^3 x \, \psi^*(\boldsymbol{x}) \Delta V(\boldsymbol{x}) \psi(\boldsymbol{x}) \tag{6.2.14}$$

where ψ is the wave function of the electron in the atom. Since we have a factor of $\delta(\boldsymbol{r})$ this shift only applies to wave functions which are nonzero at the origin, meaning it only applies to s states. The energy shift to these states is

$$\Delta E = -|\psi(0)|^2 \frac{4Z\alpha^2}{15m^2} \tag{6.2.15}$$

with $\alpha = e^2/(4\pi)$ being the **fine structure constant**.

This shift is one contribution to the Lamb shift, the difference between the energy levels $^2S_{1/2}$ and $^2P_{1/2}$ which is not predicted by the Dirac equation alone. It is not the dominant contribution to the Lamb shift. This shift is more important for muonic atoms, where the electron is replaced by a muon, since heavier external particles make the one-fermion-loop diagram more dominant, as opposed to diagrams with, say, photon loops, since these are suppressed by factors of $1/m$, with m the mass of the external particles.

6.3 Effective Charge Distribution

We can write the corrected potential as

$$V(\boldsymbol{r}) = e_1 e_2 \int d^3x \, d^3y \, \frac{\eta(\boldsymbol{x})\eta(\boldsymbol{y})}{4\pi|\boldsymbol{x} - \boldsymbol{y} + \boldsymbol{r}|} \tag{6.3.1}$$

where

$$\eta(\boldsymbol{r}) = \delta(\boldsymbol{r}) + \frac{1}{2}\hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{i\boldsymbol{k}\cdot\boldsymbol{r}}. \tag{6.3.2}$$

Note that we are implicitly dropping the Π^2 term appearing in the product $\eta(\boldsymbol{x})\eta(\boldsymbol{y})$ since this term is $\mathcal{O}(e^6)$, which is of a higher order than the one loop calculations we have been doing, and so is not physically meaningful if we don't also include two loop calculations. To see how this works expand this form of the potential, dropping the Π^2 term, giving

$$V(\boldsymbol{r}) = e_1 e_2 \int d^3x \, d^3y \, \frac{1}{4\pi|\boldsymbol{x} - \boldsymbol{y} + \boldsymbol{r}|} \left[\delta(\boldsymbol{x}) + \frac{1}{2}\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{i\boldsymbol{k}\cdot\boldsymbol{x}}\right]$$
$$\times \left[\delta(\boldsymbol{y}) + \frac{1}{2}\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{i\boldsymbol{k}\cdot\boldsymbol{y}}\right] \tag{6.3.3}$$

$$= e_1 e_2 \int d^3x \, d^3y \frac{1}{4\pi|\boldsymbol{x} - \boldsymbol{y} + \boldsymbol{r}|}\Big[\delta(\boldsymbol{x})\delta(\boldsymbol{y}) \tag{6.3.4}$$

$$+ \frac{1}{2}\delta(\boldsymbol{x})\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{-i\boldsymbol{k}\cdot\boldsymbol{y}} + \frac{1}{2}\delta(\boldsymbol{y})\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{-i\boldsymbol{k}\cdot\boldsymbol{x}}\Big]$$

$$= \frac{e_1 e_2}{4\pi|\boldsymbol{r}|} + \frac{1}{2}\int d^3y \frac{e_1 e_2}{4\pi|-\boldsymbol{y}+\boldsymbol{r}|}\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{-i\boldsymbol{k}\cdot\boldsymbol{y}}$$

$$+ \frac{1}{2}\int d^3y \frac{e_1 e_2}{4\pi|\boldsymbol{x}+\boldsymbol{r}|}\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{-i\boldsymbol{k}\cdot\boldsymbol{x}} \tag{6.3.5}$$

$$= \frac{e_1 e_2}{4\pi|\boldsymbol{r}|} + \int d^3x \frac{e_1 e_2}{4\pi|\boldsymbol{x}+\boldsymbol{r}|}\int \hat{d}^3 k \, \Pi(-\boldsymbol{k}^2)e^{-i\boldsymbol{k}\cdot\boldsymbol{x}}. \tag{6.3.6}$$

In the last step we make the transformation of variables $\boldsymbol{y} \mapsto -\boldsymbol{x}$ and identify that both integrals are the same. Now recognise that we can write the first factor in the

integral as the inverse Fourier transform of it's Fourier transform:

$$\frac{1}{4\pi|\boldsymbol{x}+\boldsymbol{r}|} = \int \hat{\mathrm{d}}^3k \, \frac{1}{|\boldsymbol{k}|^2} \mathrm{e}^{-i\boldsymbol{k}\cdot(\boldsymbol{x}+\boldsymbol{r})} \tag{6.3.7}$$

and so we get

$$V(\boldsymbol{r}) = \frac{e_1 e_2}{4\pi|\boldsymbol{r}|} + \int \hat{\mathrm{d}}^3k \, \frac{1}{|\boldsymbol{k}|^2} \Pi(-\boldsymbol{k}^2) \mathrm{e}^{-i\boldsymbol{k}\cdot\boldsymbol{r}}. \tag{6.3.8}$$

This takes the form we had in the previous section of a Coulomb potential plus the correction from one loop diagrams.

The interpretation of this rewriting of the potential is that the electron's charge distribution is a superposition of a point charge, given by the $1/|\boldsymbol{r}|$ Coulomb part of the potential, but also has some spatial distribution coming from this extra one loop term. The intuition is that this is similar to a point charge in a medium causing that medium to become polarised around it. The electron polarises the sea of virtual particles around it. This is why we call this term the vacuum polarisation, since it occurs outside of any medium.

6.4 Large Logs

In the on-shell scheme we have

$$\Pi(k^2) = \frac{e^2}{2\pi^2} \int_0^1 \mathrm{d}x \, x(1-x) \log\left[1 - \frac{x(1-x)k^2 + i\epsilon}{m^2}.\right] \tag{6.4.1}$$

In perturbation theory we expect that the one loop diagrams are small corrections to the tree level amplitude. Since $e^2 = 4\pi\alpha \approx 4\pi/137 \approx 0.09$ is small many one loop corrections are small. However this isn't enough on its own. If k^2 is large enough then the logarithm can become large. This is the problem of **large logs**.

This is a very real worry, for example, the LHC operates at $\sqrt{s} = 13\,\mathrm{TeV}$, meaning that $k^2 \approx s = (13\,\mathrm{TeV})^2$, so an electron created in this process will have $k^2/m^2 \sim 10^{14}$, so $\log(k^2/m^2) \sim 34$, which is large enough to require higher order terms to achieve the desired accuracy. We also run into this issue if we try to take the $m \to 0$ limit, which can be a useful thing to do.

This problem of large logs is worse in QCD where $\alpha_S \approx 1/10$, so the coupling doesn't provide as much suppression of higher order terms.

The way we get around this is to instead work in the $\overline{\mathrm{MS}}$ scheme, where this can still be an issue. We know that $\tilde{\mu}$ is non-physical, and so can't appear in an amplitude calculated to all orders, however $\tilde{\mu}$ does appear in truncated calculations. By carefully choosing the value of $\tilde{\mu}$ we can avoid large logs. This leads to the somewhat unsettling observation that while $\tilde{\mu}$ is non-physical it does affect the rate of "convergence" of our perturbative series, which certainly feels like it is a physical result.
